

Core Equations

Damage Model:

$$D = R_{\text{event}} \times S_{\text{event}}$$

Power Model:

$$P_{\text{net}} = P_{\text{base}} \times (1 - R_{\text{event}} \times S_{\text{event}})$$

Where:

R_{event} = event frequency

S_{event} = event severity

Lithium current primarily reduces S_{event} .

Supervisor dynamically tunes R_{event} and operating conditions.

Interpretation

The system no longer requires elimination of instability.

Instead, it shifts the regime to one where instability is tolerable.

This reframes fusion from a stability problem into a damage-management problem.
